## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.62 years for white males and 74.89 years for white females. This State ranks 14th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 530  |
| 2 White males -----                           | 532  |
| 3 White females -----                         | 534  |
| Explanation of the columns of the life table- | 529  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |      |        |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ):**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ):**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00227—out of every 1,000 reaching their 21st birthday, 2.27 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ):**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,273 will complete the first year of life and enter the second, 95,397 will reach age 21, and 42,084 will live to age 75.

**Column 4—Number dying ( $d_x$ ):**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,727 die in the first year of life, 216 in the 22d year, and 2,850 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ):**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,289. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,289 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,735,706 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,762,486.

**Column 7—Average remaining lifetime ( $e_x$ ):**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,289 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,397 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,735,706) in column 6 is the total number of years lived after attaining age 21 by the 95,397 reaching that age. This number of years divided by the number of persons (4,735,706 divided by 95,397) gives 49.64 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: OREGON, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |
| $x$ to $x + 1$                               | $q_x$                                                                     | $l_x$                                     | $d_x$                           | $L_x$                 | $T_x$                                        | $\delta_x$                                                            |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.04 years for white males and 73.13 years for white females. This State ranks 37th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 542  |
| 2 White males -----                           | 544  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00151—out of every 1,000 reaching their 21st birthday, 1.51 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,509 will complete the first year of life and enter the second, 96,028 will reach age 21, and 37,286 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,491 die in the first year of life, 145 in the 22d year, and 2,896 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,956. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,956 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,669,942 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,704,411.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,956 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,028 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,669,942) in column 6 is the total number of years lived after attaining age 21 by the 96,028 reaching that age. This number of years divided by the number of persons (4,669,942 divided by 96,028) gives 48.63 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: PENNSYLVANIA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.83 years for white males and 73.68 years for white females. This State ranks 18th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 558  |
| 2 White males -----                           | 560  |
| 3 White females -----                         | 562  |
| Explanation of the columns of the life table- | 557  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00080—out of every 1,000 reaching their 21st birthday, 0.80 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,456 will complete the first year of life and enter the second, 96,275 will reach age 21, and 38,565 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,544 die in the first year of life, 77 in the 22d year, and 2,949 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 96,236. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,236 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,748,091 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,782,972.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 96,236 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,275 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,748,091) in column 6 is the total number of years lived after attaining age 21 by the 96,275 reaching that age. This number of years divided by the number of persons (4,748,091 divided by 96,275) gives 49.32 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: RHODE ISLAND, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 65.97 years for white males and 73.93 years for white females. This State ranks 51st among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 570  |
| 2 White males -----                           | 572  |
| 3 White females -----                         | 574  |
| 4 Nonwhite males -----                        | 576  |
| 5 Nonwhite females -----                      | 578  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00152—out of every 1,000 reaching their 21st birthday, 1.52 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,325 will complete the first year of life and enter the second, 95,618 will reach age 21, and 35,560 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,675 die in the first year of life, 146 in the 22d year, and 2,719 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,545. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,545 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,568,387 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,596,568.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,545 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,618 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,568,387) in column 6 is the total number of years lived after attaining age 21 by the 95,618 reaching that age. This number of years divided by the number of persons (4,568,387 divided by 95,618) gives 47.78 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR TOTAL POPULATION: SOUTH CAROLINA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 68.35 years for white males and 75.56 years for white females. This State ranks 12th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 586  |
| 2 White males -----                           | 588  |
| 3 White females -----                         | 590  |
| Explanation of the columns of the life table- | 585  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                      | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00219—out of every 1,000 reaching their 21st birthday, 2.19 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,366 will complete the first year of life and enter the second, 95,314 will reach age 21, and 44,868 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,634 die in the first year of life, 208 in the 22d year, and 2,874 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,209. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,209 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,807,197 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,834,749.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,209 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,314 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,807,197) in column 6 is the total number of years lived after attaining age 21 by the 95,314 reaching that age. This number of years divided by the number of persons (4,807,197 divided by 95,314) gives 50.44 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: SOUTH DAKOTA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.49 years for white males and 74.38 years for white females. This State ranks 38th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 598  |
| 2 White males -----                           | 600  |
| 3 White females -----                         | 602  |
| 4 Nonwhite males -----                        | 604  |
| 5 Nonwhite females -----                      | 606  |
| Explanation of the columns of the life table- | 597  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                      | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00182—out of every 1,000 reaching their 21st birthday, 1.82 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,138 will complete the first year of life and enter the second, 95,426 will reach age 21, and 42,075 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,862 die in the first year of life, 173 in the 22d year, and 2,808 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,340. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,340 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,723,766 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,748,930.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,340 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,426 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,723,766) in column 6 is the total number of years lived after attaining age 21 by the 95,426 reaching that age. This number of years divided by the number of persons (4,723,766 divided by 95,426) gives 49.50 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: TENNESSEE, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.79 years for white males and 75.15 years for white females. This State ranks 26th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 614  |
| 2 White males -----                           | 616  |
| 3 White females -----                         | 618  |
| 4 Nonwhite males -----                        | 620  |
| 5 Nonwhite females -----                      | 622  |
| Explanation of the columns of the life table- | 613  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  | Age 65                   |       |        |                  |                  |
|------|------------------------|--------------------------|-------|--------|------------------|------------------|--------------------------|-------|--------|------------------|------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).—**The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).—**This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00184—out of every 1,000 reaching their 21st birthday, 1.84 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).—**This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,128 will complete the first year of life and enter the second, 95,297 will reach age 21, and 42,347 will live to age 75.

**Column 4—Number dying ( $d_x$ ).—**This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,872 die in the first year of life, 175 in the 22d year, and 2,793 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—**Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,209. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,209 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,755,664 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,779,053.

**Column 7—Average remaining lifetime ( $e_x$ ).—**The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,209 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,297 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,755,664) in column 6 is the total number of years lived after attaining age 21 by the 95,297 reaching that age. This number of years divided by the number of persons (4,755,664 divided by 95,297) gives 49.90 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: TEXAS, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data, at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 68.79 years for white males and 75.04 years for white females. This State ranks 6th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 630  |
| 2 White males -----                           | 632  |
| 3 White females -----                         | 634  |
| Explanation of the columns of the life table- | 629  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth              |       |        |                  |                  |                       | Age 65 |        |                  |                  |                       |                       |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).—**The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).—**This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00169—out of every 1,000 reaching their 21st birthday, 1.69 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).—**This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,849 will complete the first year of life and enter the second, 95,940 will reach age 21, and 44,583 will live to age 75.

**Column 4—Number dying ( $d_x$ ).—**This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,151 die in the first year of life, 162 in the 22d year, and 2,880 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—**Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,858. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,858 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,840,556 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,879,020.

**Column 7—Average remaining lifetime ( $e_x$ ).—**The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,858 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,940 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,840,556) in column 6 is the total number of years lived after attaining age 21 by the 95,940 reaching that age. This number of years divided by the number of persons (4,840,556 divided by 95,940) gives 50.45 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: UTAH, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 66.95 years for white males and 74.02 years for white females. This State ranks 22nd among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 642  |
| 2 White males -----                           | 644  |
| 3 White females -----                         | 646  |
| Explanation of the columns of the life table- | 641  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth         |       |        |                  |                  |                  | Age 65 |        |                  |                  |                  |                  |
|------|------------------------|------------------|-------|--------|------------------|------------------|------------------|--------|--------|------------------|------------------|------------------|------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00180—out of every 1,000 reaching their 21st birthday, 1.80 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,108 will complete the first year of life and enter the second, 95,327 will reach age 21, and 39,104 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,892 die in the first year of life, 171 in the 22d year, and 3,040 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,242. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,242 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,671,459 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,694,945.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,242 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,327 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,671,459) in column 6 is the total number of years lived after attaining age 21 by the 95,327 reaching that age. This number of years divided by the number of persons (4,671,459 divided by 95,327) gives 49.00 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: VERMONT, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.20 years for white males and 74.37 years for white females. This State ranks 41st among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 654  |
| 2 White males -----                           | 656  |
| 3 White females -----                         | 658  |
| 4 Nonwhite males -----                        | 660  |
| 5 Nonwhite females -----                      | 662  |
| Explanation of the columns of the life table- | 653  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth         |       |        |                  |                  |                  | Age 65 |        |                  |                  |                  |                  |
|------|------------------------|------------------|-------|--------|------------------|------------------|------------------|--------|--------|------------------|------------------|------------------|------------------|
|      |                        | Total population | White |        | Nonwhite         |                  | Total population | White  |        | Nonwhite         |                  | Total population | Total population |
|      |                        |                  | Male  | Female | Male             | Female           |                  | Male   | Female | Male             | Female           |                  |                  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00136—out of every 1,000 reaching their 21st birthday, 1.36 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,239 will complete the first year of life and enter the second, 95,661 will reach age 21, and 39,335 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,761 die in the first year of life, 131 in the 22d year, and 2,835 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,595. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,595 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,691,774 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,719,935.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,595 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,661 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,691,774) in column 6 is the total number of years lived after attaining age 21 by the 95,661 reaching that age. This number of years divided by the number of persons (4,691,774 divided by 95,661) gives 49.05 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: VIRGINIA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.92 years for white males and 74.90 years for white females. This State ranks 11th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 670  |
| 2 White males -----                           | 672  |
| 3 White females -----                         | 674  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00149—out of every 1,000 reaching their 21st birthday, 1.49 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,418 will complete the first year of life and enter the second, 95,808 will reach age 21, and 41,562 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,582 die in the first year of life, 143 in the 22d year, and 2,841 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,736. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,736 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,761,092 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,792,314.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,736 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,808 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,761,092) in column 6 is the total number of years lived after attaining age 21 by the 95,808 reaching that age. This number of years divided by the number of persons (4,761,092 divided by 95,808) gives 49.69 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WASHINGTON, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 66.55 years for white males and 73.50 years for white females. This State ranks 34th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 682  |
| 2 White males -----                           | 684  |
| 3 White females -----                         | 686  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).—**The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).—**This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00235—out of every 1,000 reaching their 21st birthday, 2.35 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).—**This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,133 will complete the first year of life and enter the second, 95,299 will reach age 21, and 39,397 will live to age 75.

**Column 4—Number dying ( $d_x$ ).—**This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,867 die in the first year of life, 224 in the 22d year, and 2,631 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—**Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,187. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,187 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,630,686 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,655,036.

**Column 7—Average remaining lifetime ( $e_x$ ).—**The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,187 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,299 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,630,686) in column 6 is the total number of years lived after attaining age 21 by the 95,299 reaching that age. This number of years divided by the number of persons (4,630,686 divided by 95,299) gives 48.59 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WEST VIRGINIA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 68.45 years for white males and 74.56 years for white females. This State ranks 8th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 694  |
| 2 White males -----                           | 696  |
| 3 White females -----                         | 698  |
| Explanation of the columns of the life table- | 693  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).—**The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).—**This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00200—out of every 1,000 reaching their 21st birthday, 2.00 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).—**This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,536 will complete the first year of life and enter the second, 95,761 will reach age 21, and 43,222 will live to age 75.

**Column 4—Number dying ( $d_x$ ).—**This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,464 die in the first year of life, 192 in the 22d year, and 2,978 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—**Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,665. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,665 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,810,686 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,844,595.

**Column 7—Average remaining lifetime ( $e_x$ ).—**The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,665 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,761 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,810,686) in column 6 is the total number of years lived after attaining age 21 by the 95,761 reaching that age. This number of years divided by the number of persons (4,810,686 divided by 95,761) gives 50.24 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WISCONSIN, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 66.62 years for white males and 74.47 years for white females. This State ranks 28th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 706  |
| 2 White males -----                           | 708  |
| 3 White females -----                         | 710  |
| Explanation of the columns of the life table- | 705  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  | Age 65                   |       |        |                  |                  |
|------|------------------------|--------------------------|-------|--------|------------------|------------------|--------------------------|-------|--------|------------------|------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00373—out of every 1,000 reaching their 21st birthday, 3.73 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 96,889 will complete the first year of life and enter the second, 94,311 will reach age 21, and 41,600 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 3,111 die in the first year of life, 352 in the 22d year, and 2,862 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 94,134. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 94,134 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,648,902 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,662,234.

**Column 7—Average remaining lifetime ( $e'_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 94,134 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 94,311 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,648,902) in column 6 is the total number of years lived after attaining age 21 by the 94,311 reaching that age. This number of years divided by the number of persons (4,648,902 divided by 94,311) gives 49.29 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: WYOMING, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |
