## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 66.47 years for white males and 74.17 years for white females. This State ranks 35th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 378  |
| 2 White males -----                           | 380  |
| 3 White females -----                         | 382  |
| Explanation of the columns of the life table- | 377  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                      | At Birth              |       |        |                  |                  |                       | Age 65 |        |                  |                  |                       |                       |
|------|---------------------------|-----------------------|-------|--------|------------------|------------------|-----------------------|--------|--------|------------------|------------------|-----------------------|-----------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00299—out of every 1,000 reaching their 21st birthday, 2.99 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,241 will complete the first year of life and enter the second, 94,985 will reach age 21, and 39,438 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,759 die in the first year of life, 285 in the 22d year, and 2,729 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 94,842. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 94,842 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,622,350 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,646,963.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 94,842 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 94,985 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,622,350) in column 6 is the total number of years lived after attaining age 21 by the 94,985 reaching that age. This number of years divided by the number of persons (4,622,350 divided by 94,985) gives 48.66 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: MONTANA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 69.08 years for white males and 75.68 years for white females. This State ranks 1st among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 390  |
| 2 White males -----                           | 392  |
| 3 White females -----                         | 394  |
| Explanation of the columns of the life table- | 389  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00169—out of every 1,000 reaching their 21st birthday, 1.69 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,485 will complete the first year of life and enter the second, 95,810 will reach age 21, and 45,418 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,515 die in the first year of life, 162 in the 22d year, and 2,902 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,730. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,730 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,874,273 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,907,645.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,730 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,810 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,874,273) in column 6 is the total number of years lived after attaining age 21 by the 95,810 reaching that age. This number of years divided by the number of persons (4,874,273 divided by 95,810) gives 50.87 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEBRASKA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 64.55 years for white males and 72.68 years for white females. This State ranks 49th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 402  |
| 2 White males -----                           | 404  |
| 3 White females -----                         | 406  |
| Explanation of the columns of the life table- | 401  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |
|------|------------------------|--------------------------|-------|--------|------------------|------------------|--------------------------|--------|--------|------------------|------------------|--------------------------|--------------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00243—out of every 1,000 reaching their 21st birthday, 2.43 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 96,854 will complete the first year of life and enter the second, 94,823 will reach age 21, and 33,505 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 3,146 die in the first year of life, 231 in the 22d year, and 2,753 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 94,708. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 94,708 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,438,706 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,455,450.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 94,708 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 94,823 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,438,706) in column 6 is the total number of years lived after attaining age 21 by the 94,823 reaching that age. This number of years divided by the number of persons (4,438,706 divided by 94,823) gives 46.81 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEVADA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.05 years for white males and 74.04 years for white females. This State ranks 19th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 414  |
| 2 White males -----                           | 416  |
| 3 White females -----                         | 418  |
| Explanation of the columns of the life table- | 413  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth         |       |        |                  |                  |                  | Age 65 |        |                  |                  |                  |                  |
|------|------------------------|------------------|-------|--------|------------------|------------------|------------------|--------|--------|------------------|------------------|------------------|------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00182—out of every 1,000 reaching their 21st birthday, 1.82 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,326 will complete the first year of life and enter the second, 95,429 will reach age 21, and 38,407 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,674 die in the first year of life, 174 in the 22d year, and 2,945 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,341. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,341 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,677,433 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,705,045.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,341 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,429 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,677,433) in column 6 is the total number of years lived after attaining age 21 by the 95,429 reaching that age. This number of years divided by the number of persons (4,677,433 divided by 95,429) gives 49.01 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEW HAMPSHIRE, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |
| x to x + 1                                   | $q_x$                                                                     | $l_x$                                     | $d_x$                           | $L_x$                 | $T_x$                                        | $\delta_x$                                                            |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.64 years for white males and 73.43 years for white females. This State ranks 30th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 426  |
| 2 White males -----                           | 428  |
| 3 White females -----                         | 430  |
| 4 Nonwhite males -----                        | 432  |
| 5 Nonwhite females -----                      | 434  |
| Explanation of the columns of the life table- | 425  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth         |       |        |                  |                  |                  | Age 65 |        |                  |                  |                  |                  |
|------|------------------------|------------------|-------|--------|------------------|------------------|------------------|--------|--------|------------------|------------------|------------------|------------------|
|      |                        | Total population | White |        | Nonwhite         |                  | Total population | White  |        | Nonwhite         |                  | Total population | Total population |
|      |                        |                  | Male  | Female | Male             | Female           |                  | Male   | Female | Male             | Female           |                  |                  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00136—out of every 1,000 reaching their 21st birthday, 1.36 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,600 will complete the first year of life and enter the second, 96,252 will reach age 21, and 38,369 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,400 die in the first year of life, 131 in the 22d year, and 2,908 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 96,187. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 96,187 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,726,480 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,763,632.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 96,187 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,252 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,726,480) in column 6 is the total number of years lived after attaining age 21 by the 96,252 reaching that age. This number of years divided by the number of persons (4,726,480 divided by 96,252) gives 49.11 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEW JERSEY, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 66.77 years for white males and 73.39 years for white females. This State ranks 36th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 442  |
| 2 White males -----                           | 444  |
| 3 White females -----                         | 446  |
| Explanation of the columns of the life table- | 441  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                      | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |      |        |
|------|---------------------------|--------------------------|-------|--------|------------------|------------------|--------------------------|--------|--------|------------------|------------------|------|--------|

<sup>1</sup> Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00252—out of every 1,000 reaching their 21st birthday, 2.52 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 96,543 will complete the first year of life and enter the second, 94,213 will reach age 21, and 42,366 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 3,457 die in the first year of life, 238 in the 22d year, and 2,593 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 94,094. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 94,094 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,669,811 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,677,455.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 94,094 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 94,213 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,669,811) in column 6 is the total number of years lived after attaining age 21 by the 94,213 reaching that age. This number of years divided by the number of persons (4,669,811 divided by 94,213) gives 49.57 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEW MEXICO, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.39 years for white males and 73.31 years for white females. This State ranks 33rd among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 454  |
| 2 White males -----                           | 456  |
| 3 White females -----                         | 458  |
| 4 Nonwhite males -----                        | 460  |
| 5 Nonwhite females -----                      | 462  |
| Explanation of the columns of the life table- | 453  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth         |       |        |                  |                  | Age 65           |       |        |                  |                  |
|------|------------------------|------------------|-------|--------|------------------|------------------|------------------|-------|--------|------------------|------------------|
|      |                        | Total population | White |        | Nonwhite         |                  | Total population | White |        | Nonwhite         |                  |
|      |                        |                  | Male  | Female | Male             | Female           |                  | Male  | Female | Male             | Female           |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00149—out of every 1,000 reaching their 21st birthday, 1.49 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,563 will complete the first year of life and enter the second, 96,067 will reach age 21, and 38,269 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,437 die in the first year of life, 143 in the 22d year, and 2,927 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,996. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,996 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,704,187 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,739,384.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,996 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 96,067 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,704,187) in column 6 is the total number of years lived after attaining age 21 by the 96,067 reaching that age. This number of years divided by the number of persons (4,704,187 divided by 96,067) gives 48.97 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NEW YORK, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 66.94 years for white males and 74.74 years for white females. This State ranks 43rd among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 470  |
| 2 White males -----                           | 472  |
| 3 White females -----                         | 474  |
| 4 Nonwhite males -----                        | 476  |
| 5 Nonwhite females -----                      | 478  |
| Explanation of the columns of the life table- | 469  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |      |        |
|------|------------------------|--------------------------|-------|--------|------------------|------------------|--------------------------|--------|--------|------------------|------------------|------|--------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

*Column 1—Year of age ( $x$  to  $x + 1$ ).—*The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

*Column 2—Proportion dying ( $q_x$ ).—*This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00174—out of every 1,000 reaching their 21st birthday, 1.74 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

*Column 3—Number surviving ( $l_x$ ).—*This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,413 will complete the first year of life and enter the second, 95,650 will reach age 21, and 39,589 will live to age 75.

*Column 4—Number dying ( $d_x$ ).—*This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,587 die in the first year of life, 167 in the 22d year, and 2,744 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

*Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—*Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,566. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,566 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,662,760 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,693,631.

*Column 7—Average remaining lifetime ( $e_x$ ).—*The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,566 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,650 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,662,760) in column 6 is the total number of years lived after attaining age 21 by the 95,650 reaching that age. This number of years divided by the number of persons (4,662,760 divided by 95,650) gives 48.75 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NORTH CAROLINA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 69.16 years for white males and 75.33 years for white females. This State ranks 5th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 486  |
| 2 White males -----                           | 488  |
| 3 White females -----                         | 490  |
| Explanation of the columns of the life table- | 485  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                      | At Birth                 |       |        |                  |                  |                          | Age 65 |        |                  |                  |                          |                          |
|------|---------------------------|--------------------------|-------|--------|------------------|------------------|--------------------------|--------|--------|------------------|------------------|--------------------------|--------------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).—**The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).—**This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00168—out of every 1,000 reaching their 21st birthday, 1.68 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).—**This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,416 will complete the first year of life and enter the second, 95,605 will reach age 21, and 46,484 will live to age 75.

**Column 4—Number dying ( $d_x$ ).—**This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,584 die in the first year of life, 160 in the 22d year, and 2,975 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—**Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,525. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,525 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,886,101 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,916,040.

**Column 7—Average remaining lifetime ( $e_x$ ).—**The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,525 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,605 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,886,101) in column 6 is the total number of years lived after attaining age 21 by the 95,605 reaching that age. This number of years divided by the number of persons (4,886,101 divided by 95,605) gives 51.11 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: NORTH DAKOTA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.74 years for white males and 73.92 years for white females. This State ranks 23rd among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 498  |
| 2 White males -----                           | 500  |
| 3 White females -----                         | 502  |
| 4 Nonwhite males -----                        | 504  |
| 5 Nonwhite females -----                      | 506  |
| Explanation of the columns of the life table- | 497  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth              |       |        |                  |                  | Age 65                |       |        |                  |                  |
|------|------------------------|-----------------------|-------|--------|------------------|------------------|-----------------------|-------|--------|------------------|------------------|

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).**—The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).**—This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00158—out of every 1,000 reaching their 21st birthday, 1.58 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).**—This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,490 will complete the first year of life and enter the second, 95,951 will reach age 21, and 40,137 will live to age 75.

**Column 4—Number dying ( $d_x$ ).**—This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,510 die in the first year of life, 152 in the 22d year, and 2,895 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).**—Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,875. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,875 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,740,620 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,774,311.

**Column 7—Average remaining lifetime ( $e_x$ ).**—The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,875 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,951 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,740,620) in column 6 is the total number of years lived after attaining age 21 by the 95,951 reaching that age. This number of years divided by the number of persons (4,740,620 divided by 95,951) gives 49.41 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: OHIO, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
|----------------------------------------------|---------------------------------------------------------------------------|-------------------------------------------|---------------------------------|-----------------------|----------------------------------------------|-----------------------------------------------------------------------|
| Period of life between two exact ages stated | Proportion of persons alive at beginning of year of age dying during year | Number living at beginning of year of age | Number dying during year of age | In year of age        | In this year of age and all subsequent years | Average number of years of life remaining at beginning of year of age |
| (1)                                          | (2)                                                                       | (3)                                       | (4)                             | (5)                   | (6)                                          | (7)                                                                   |

## STATE LIFE TABLES: 1959-61

This report contains the 1959-61 detailed life tables for this State. Separate life tables are included for the total population and for white males, white females, nonwhite males, and nonwhite females.

These tables are based on the 1960 census of population and on the average annual number of resident deaths during the 3-year period 1959-61. For the ages under 2, where enumeration in the census is known to be incomplete, use was made of reported births for the years 1957-61. Because of the unreliability of the available data at the oldest ages, "proportions dying" at ages 95 and over are not based on actual statistics for these ages (and, in fact, have the same numerical values in all the tables). Values at ages 85-94 have also been adjusted to make the numbers progress smoothly with increasing age. Therefore, the figures at ages 85 and above may not represent actual conditions and must be regarded as approximate. The population and death statistics for ages under 85, which were used in the calculation of the life tables, are known to be subject to certain errors. However, the only such error that was considered to be serious enough to require adjustment prior to the calculation of the life tables was apparent inaccuracy in age reporting among nonwhites in the neighborhood of age 60. In order to avoid anomalous life table values the nonwhite population at ages 55-64 was reallocated between the 5-year age groups 55-59 and 60-64.

A later publication will contain a complete description of the adjustments made in the basic data and of the methods and formulas by which the life tables were prepared.

The life table assumes that a hypothetical cohort traced from birth until the death of the last survivor is subject, throughout its existence, to the age by age mortality rates observed in a certain population or population subdivision during a specified period. For example, table 2 is a life table for white males; it shows the progress of a cohort starting with 100,000 live births and subject, during its passage through successive years of age, to the average annual mortality rates observed among white males in this State in the 3-year period 1959-61.

One of the columns of this life table shows the average number of years of life remaining to those in the cohort who attain each birthday. This average remaining lifetime is commonly called the expectation of life, and the expectation of life at birth is frequently used as a measure of comparative longevity. According to the 1959-61 life tables for this State, the expectation of life at birth is 67.95 years for white males and 75.44 years for white females. This State ranks 13th among the 50 States and the District of Columbia in the expectation of life at birth for the total population. The text table on the following page shows the average remaining lifetime at birth and at 65 years for the United States, each State, and the District of Columbia.

| Table No.                                     | Page |
|-----------------------------------------------|------|
| 1 Total population-----                       | 514  |
| 2 White males-----                            | 516  |
| 3 White females-----                          | 518  |
| 4 Nonwhite males-----                         | 520  |
| 5 Nonwhite females-----                       | 522  |
| Explanation of the columns of the life table- | 513  |

**AVERAGE REMAINING LIFETIME IN YEARS AT BIRTH AND AT AGE 65, BY COLOR AND SEX: UNITED STATES AND EACH STATE  
IN RANK ORDER, 1959-61**

(States are ranked according to the expectation of life at birth for the total population)

| Rank | Area                   | At Birth         |       |        |                  |                  |                  | Age 65 |        |                  |                  |                  |                  |
|------|------------------------|------------------|-------|--------|------------------|------------------|------------------|--------|--------|------------------|------------------|------------------|------------------|
|      |                        | Total population | White |        | Nonwhite         |                  | Total population | White  |        | Nonwhite         |                  | Total population | Total population |
|      |                        |                  | Male  | Female | Male             | Female           |                  | Male   | Female | Male             | Female           |                  |                  |

<sup>1</sup>Not computed because fewer than 2,000 nonwhite female or male deaths were registered in the 3-year period 1959-61.

## EXPLANATION OF THE COLUMNS OF THE LIFE TABLE

**Column 1—Year of age ( $x$  to  $x + 1$ ).—**The year of age, shown in column 1, is the interval of one year between the two exact ages indicated. For instance, "21-22" indicates the interval between the 21st birthday and the 22d, in other words the 22d year of life.

**Column 2—Proportion dying ( $q_x$ ).—**This column shows the proportion of the members of the life-table cohort alive at the beginning of the indicated year of age who will die before reaching the next birthday. For example, for white males in the year of age 21-22, the proportion dying is .00172—out of every 1,000 reaching their 21st birthday, 1.72 would die before reaching the 22d birthday, on the basis of the mortality rates of 1959-61 for white males in this State.

**Column 3—Number surviving ( $l_x$ ).—**This column shows the number of persons, starting with a cohort of 100,000 live births, who survive to the birthday marking the beginning of the indicated year of age. Thus, out of 100,000 babies born alive in the cohort represented by table 2, 97,532 will complete the first year of life and enter the second, 95,630 will reach age 21, and 42,523 will live to age 75.

**Column 4—Number dying ( $d_x$ ).—**This column shows the number dying in the indicated year of age out of 100,000 live births. Thus out of 100,000 born alive in the cohort of table 2, 2,468 die in the first year of life, 164 in the 22d year, and 2,734 in the 76th year. Each figure in column 4 is the difference between two successive figures in column 3.

**Columns 5 and 6—Stationary population ( $L_x$  and  $T_x$ ).—**Suppose that a group of 100,000 persons like that assumed in columns 3 and 4 is born each year, and that the proportion dying in each such group in each year of age throughout the lives of the members is exactly that shown in column 2. If there were no migration and if the births were evenly distributed over the calendar year, the survivors of these births would constitute what is called a stationary population—stationary because in such a population the number of persons living in any given year of age would never change. When an individual left an age, whether by death or by growing older and entering the next higher age, his place would immediately be taken by someone entering from the next lower age. Thus, a census taken at any time in such a stationary community would always show the same total population and the same numerical distribution of that population among the various ages. In such a stationary population supported by 100,000 annual births, column

3 shows the number of persons who, each year, reach the birthday that marks the beginning of the year of age indicated in column 1, and column 4 shows the number of persons who die each year in that year of age.

Column 5,  $L_x$ , shows the number of persons in the stationary population in the indicated year of age. For example, the figure shown in table 2 for the year of age 21-22 is 95,548. This means that in a stationary population supported by 100,000 annual births and with proportions dying at each age always in accordance with column 2, a census taken on any date would show 95,548 persons at age 21 (that is, between exact ages 21 and 22 years).

Column 6,  $T_x$ , shows the total number of persons in the stationary population (column 5) in the indicated year of age and all subsequent years of age. For example, in the stationary population of white males described in the preceding paragraph, column 6 shows that there would be at any given moment 4,764,176 persons who have reached their 21st birthday. The population at all ages 0 and above (in other words, the total stationary population of white males) would be 6,794,967.

**Column 7—Average remaining lifetime ( $e_x$ ).—**The average remaining lifetime (also called expectation of life) at any given age is the average number of years remaining to be lived by those surviving to that age, on the basis of a given set of age-specific rates of dying. In order to relate these figures to the preceding columns of the life table, it is necessary to observe that the figures in column 5 can also be interpreted in terms of a single life-table cohort without introducing the concept of a stationary population. From this point of view, each figure in column 5 represents the total time (in years) lived between the two indicated birthdays by all those reaching the earlier birthday among the survivors of a cohort of 100,000 live births. Thus, the figure 95,548 for white males in this State in the year of age 21-22 is the total number of years lived between their 21st and 22d birthdays by the 95,630 (column 3) who reach the 21st birthday, out of the original cohort of 100,000, and the corresponding figure (4,764,176) in column 6 is the total number of years lived after attaining age 21 by the 95,630 reaching that age. This number of years divided by the number of persons (4,764,176 divided by 95,630) gives 49.82 years as the average remaining lifetime at age 21 for white males in this State.

TABLE 1. LIFE TABLE FOR THE TOTAL POPULATION: OKLAHOMA, 1959-61

| AGE IN YEARS                                 | PROPORTION DYING                                                          | OF 100,000 BORN ALIVE                     |                                 | STATIONARY POPULATION |                                              | AVERAGE REMAINING LIFETIME                                            |
